Approximation Algorithms

Approx_Vertex_Cover is a 2-approximation algorithm.

```
Approx_Vertex_Cover(G) /* G = (V,E) */
1    C = ∅
2    E' = E
3    while E' ≠ ∅
4         let (u,v) be an arbitrary edge of E'
5         C = C ∪ {u,v}
6         remove from E' every edge joining either u or v
7    return C
```
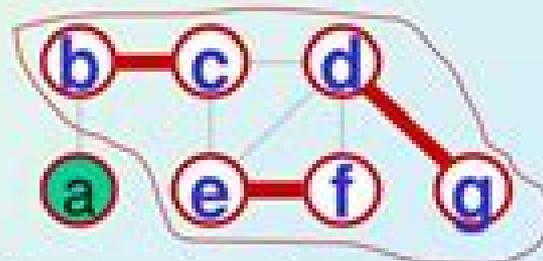

Proof:

Consider line 4. Suppose there are totally |A| edges considered in line 4.

Then $|C^*| \geq |A|$

But $|C| = 2|A|$

Hence $|C| = 2|A| \leq 2|C^*|$

Near-optimal solution (C)   Optimal solution (C*)

cannot perform computations with arbitrary precision and we have to truncate the representation of real numbers In other cases we use to approximate com plex mathematical objects by simpler ones for example we sometimes represent non linear functions by means of piecewise linear ones The need to solve difficult optimization problems is another reason that forces us to deal with approximation In particular when a problem is computationally hard i e the only way we know to solve it is by making use of an algorithm that runs in exponential time it may be practically unfeasible to try to compute the exact solution because it might require months or years of machine time even with the help of powerful parallel computers In such cases we may decide to restrict ourselves to compute a solution that though not being an optimal one nevertheless is close to the optimum and may be determined in polynomial time We call this type of solution an approximate solution and the corresponding algorithm a polynomial time approximation algorithm Most combinatorial optimization problems of great practical relevance are indeed computationally intractable in the above sense In formal terms they are classified as Np hard optimization problems   *Algorithms and Computation* ,2005
