

Animal Structure and Function - MAMMALS

LS1.A: Structure and Function - All organisms have external parts. Different animals use their body parts in different ways to see, hear, grasp objects, protect themselves, move from place to place, and seek, find, and take in food, water and air.

Mammals are covered with hair or fur (except for marine mammals), which helps to keep them warm (or cool). Fur color can help them hide from predators or sneak up on prey.

Mammals use their mouths, teeth, hands, paws and claws to grasp things, carry young, tear food, and defend themselves and their family members.

Mammals move from place to place by walking, running, swimming, jumping or flying (bats). They move to escape predators, chase prey, stay together in a herd and find food, shelter, and mates.

Mammals use hearing, vision and sense of smell (these vary greatly between species) to find food and mates, care for young and escape predators.

Female **mammals** have mammary glands, so can feed helpless newborns nutritious milk.

The ecological theatre of life is structured by the concept of the fundamental niche which defines the potential ecological range of a species in the absence of biotic constraints. Since the rapid diversification of metazoans during the Cambrian Explosion, animal lineages have undergone extensive morphological and ecological differentiation with ancestral body plans repeatedly modified to produce the vast structural and functional complexity seen in modern ecosystems. A key evolutionary process behind this diversity is adaptive radiation, where a single ancestral lineage rapidly diversifies into multiple species occupying different ecological niches. This process is driven by factors such as mutation, limited gene flow, polyploidy, developmental plasticity, and ecological opportunities, resulting in significant phenotypic variation and trophic specialization. To understand this complexity, zoology increasingly integrates comparative embryology, paleobiology, evolutionary developmental biology, and molecular systematics. Taxonomic relationships are shaped not only by genetic isolation but also by environmental influences, developmental pathways, and physiological integration. In vertebrates, for example, endocrine regulation and neural coordination play critical roles in organ development, cellular differentiation, and morphogenesis. Evolutionary pressures act throughout an organism's life cycle, influencing reproductive strategies, life history traits, and population dynamics. From simple invertebrates to complex vertebrates, adaptations reflect evolutionary optimization within specific ecological contexts. This book emphasizes that zoological principles and anatomical concepts must be understood within a clear evolutionary framework, moving beyond simple classification to present an integrated view of comparative anatomy, physiology, taxonomy, ecology, and evolutionary theory, aligned with modern scientific understanding.
