

# Applications of Reinforcement Learning in Database Indexing: A Research Review

Database indexing is a critical yet complex aspect of database management, traditionally requiring substantial expertise from database administrators (DBAs). The emergence of machine learning techniques, particularly reinforcement learning (RL), has opened new pathways for automating this process. This review examines key research contributions applying reinforcement learning techniques to database indexing problems, highlighting methodologies, performance improvements, and future directions in this rapidly evolving field.

## Fundamentals of RL in Database Indexing Systems

Reinforcement learning provides a promising framework for automating database indexing by framing it as a sequential decision-making problem. In this paradigm, the RL agent learns to make indexing decisions by interacting with the database environment and receiving feedback on performance outcomes.

Traditional database indexing typically relies on database administrators with specialized knowledge or advisory tools that provide recommendations based on statistics. These approaches often face limitations, as statistics can only partially capture complex workload patterns, and manual tuning is time-consuming and error-prone<sup>[1]</sup>. RL approaches aim to overcome these limitations by learning optimal indexing strategies through repeated interaction with the database environment.

The core components of applying RL to database indexing include defining the state representation (typically incorporating workload characteristics and current index configuration), the action space (creating or removing indexes on specific columns), and the reward function (usually based on query performance improvements)<sup>[2]</sup>. These components must be carefully designed to enable effective learning. For instance, in the NoDBA approach, the state incorporates both workload information and current index configuration, while actions involve creating indexes on particular columns, and rewards are positive when a new index configuration improves performance compared to previous states<sup>[3]</sup>.

The application of RL to database indexing represents a significant shift from traditional approaches, as it enables systems to continuously learn and adapt to changing workload patterns, potentially outperforming static configurations determined by heuristic methods or even experienced DBAs.
