

Introduction to Mathematica: Solving Differential Equations

Mathematica can solve many ordinary, nonlinear, and partial differential equations in one or more variables. Differential equations are handled using the `DSolve` and `NDSolve` commands which produce analytical and numerical solutions, respectively. Equations may be solved with or without boundary or initial conditions however the number of boundary conditions will determine the number of unknown constants.

`DSolve` has the format

`DSolve[expressions, function names, variable names]`

where an expressions in the variable x of the function y must contain statements of the form $y[x]$ or $y'[x]$ to denote the function and its derivatives. To solve systems of equations or equations in more than one variable lists of expressions, function names, and/or variable names may be passed to `DSolve` using `{}` brackets.

Begin by entering the following equation into Mathematica:

```
eq1 = y[x]+y'[x]==0
```

What is the solution to this equation? You can find the solution to this equation by entering

```
dsol = DSolve[eq1, y, x]
```

Note that the solution contains an arbitrary constant called `C[1]`. Boundary conditions are implemented by adding their definitions to the expression in the call to `DSolve`. For example try

```
dsolbc=DSolve[{eq1, y[0]==1}, y, x]
```

What is the boundary condition being enforced here?

The solution to the problem is returned as a *Pure Function* which means that it is a local assignment to a generic function that is given the name of the function-argument supplied to `DSolve`. In other words, the solution is an assignment to a variable. This is a bit tricky. To access the results try typing

```
y[a]/.dsolbc
```

which says "substitute the first item in `dsolbc` into $y[a]$ ". Mathematica pulls the solution from `dsolbc`, replaces the value of y with this value (since the substitution in the solution is for y), then gives a to the new function for evaluation. Plotting is similar only we must use the variable over which we wish to plot as the argument to the function y .

```
Plot[y[x]/.dsolbc, {x, -10, 10}]
```

Finally, we can use basic substitution using `/.` to check our answer. Try this one own your own.

Next, work with a more difficult equation

```
eq2 =y''[x]+x y'[x]+y[x]==x
```

Solve this equation using Mathematica first without boundary conditions.
